## RESEARCH MEMORANDUM

PRESSURES AND ASSOCIATED AERODYNAMIC AND LOAD  
CHARACTERISTICS FOR TWO BODIES OF  
REVOLUTION AT TRANSONIC SPEEDS

By Harold L. Robinson

## SUMMARY

Analysis of the results obtained from a transonic wind-tunnel investigation of two bodies of revolution having the same nose shape, one incorporating a cylindrical afterbody and the other incorporating a curved afterbody, indicated that the pressures over the forward portions of the bodies were the same, whereas, the induced velocities over the rearward portions of the curved body were greater than those over the cylindrical body. However, the cross-section normal loads were greater over the rearward portions of the cylindrical body. Variation of the aerodynamic characteristics with Mach number was rather small for both bodies. The cylindrical body exhibits better stability characteristics than the curved body. The theory of NACA Rep. 1048 regarding the aerodynamic characteristics of the bodies is in fair agreement with the results of this paper.

## INTRODUCTION

A detailed study of the pressures and resulting forces for a body of revolution, designated "curved body" in this report, at transonic speeds has been presented in reference 1.

The present tests were undertaken in order to provide aerodynamic load data for a body of revolution having an ogive nose and cylindrical afterbody and to compare the aerodynamic characteristics of this body with the body of reference 1 at transonic speeds. The body used in the present test is designated "cylindrical body" herein. A comparison of various theoretical aerodynamic parameters with experimental values is included.

The tests reported herein were made for a Mach number range from 0.6 to 1.13 and an angle-of-attack range from  $0^\circ$  to  $20^\circ$ . The Reynolds number

~~CONFIDENTIAL~~

range corresponding to the Mach number range varied from  $3.3 \times 10^6$  to  $3.9 \times 10^6$  per foot of length.

### SYMBOLS

$A_p$	plan-form area of body
$C_{M_F}$	pitching-moment coefficient around the nose, based on maximum body cross-sectional area and body length
$C_{N_F}$	normal-force coefficient, based on maximum body cross-sectional area
$c_{d_C}$	section drag coefficient of an infinite cylinder
$c_n$	transverse section normal-force coefficient, $\frac{N_t}{qD d(x)}$
$c_{nn}$	meridian load coefficient, $\frac{N_n}{qLR_{max} d(\theta)}$
D	diameter of body at any station
L	length of body
M	Mach number
$N_n$	elemental force on meridian body section of width $R d(\theta)$ (force vector is normal to body axis and makes an angle $\theta$ with vertical plane of symmetry)
$N_t$	elemental force on transverse body section of length $d(x)$ (force vector is normal to horizontal plane of symmetry)
P	pressure coefficient
Q	volume of body
q	dynamic pressure
R	radius of body at any station
$S_b$	base area of body

x	distance from nose of model, positive rearward
$x_m$	moment center
$x_p$	centroid of body plan-form area
$x_{cp}$	center-of-pressure location
y	distance from vertical plane of symmetry
$\alpha$	angle of attack
$\eta$	ratio of the drag coefficient of a finite cylinder to the section drag coefficient of an infinite cylinder at $\alpha = 90^\circ$
$\theta$	meridian station, $0^\circ$ at top

## Subscripts:

max	maximum value
L	lower surface
U	upper surface

APPARATUS AND METHODSTunnel

All the data discussed herein were obtained from tests conducted in the Langley 8-foot transonic tunnel. At present, this tunnel has a dodecagonal slotted test section and is capable of continuously variable operation through the speed range up to a Mach number of 1.14. A test section used previously in this tunnel did not incorporate slots, but had a closed throat. All the data for the cylindrical body and most of the data for the curved body were obtained from tests in the slotted test section. A small portion of the data for the curved body was obtained from tests in the closed-throat test section.

Tunnel-wall-interference corrections were not applied to the data obtained from tests in the slotted test section because choking and blockage effects are negligible, especially for the small ratio of model to tunnel size of the present tests. Effects of wall-reflected disturbances have been reduced by offsetting the model from the tunnel center line.

~~CONFIDENTIAL~~

NACA RM 153L28a

### Bodies

A drawing of the two bodies is presented in figure 1. The cylindrical body has the same dimensions as body D of reference 2. The curved body is the same body as that used in references 1 and 3 and is similar to, but slightly longer than, body A of reference 2. Both the curved and cylindrical bodies have the same dimensions forward of the 20-inch body station.

Each of the models was instrumented with six rows of orifices spaced along meridians of the body. Each row contained 20 or more orifices. The relative size of the stings employed to support the model in the tunnel is indicated in figure 1.

### Measurements

Pressure.-- The pressures existing on the surface of the cylindrical body were measured by connecting the orifices to a multitubed manometer. In order to determine the forces on the model, these pressures were integrated as discussed in the section of this report entitled "Presentation of Results." The pressure data and associated aerodynamic parameters for the curved body were obtained from references 1 and 3.

The repeatability of the pressure data presented herein as affected by the pressure measurements, angle of attack, orifice size and location, and other factors may be judged from figure 2. The largest errors occur near the nose where they are as large as  $\Delta P = \pm 0.015$ . The accuracy is much better over the remainder of the body. The average error, as determined from the data presented in figure 2, is  $\Delta P = \pm 0.005$ .

Angle of attack.-- The angle of attack for the cylindrical body was measured by an electrical strain-gage pendulum device mounted internally near the base of the support sting. Sting and model deflections occurring ahead of this point, due to forces and moments acting on the model, were determined from static tests. These corrections were applied to the angles of attack, although the maximum deflections occurring during the investigation were approximately  $0.1^\circ$ . The angles of attack were also corrected for the approximately  $0.1^\circ$  upflow existing in the Langley 8-foot transonic tunnel. The absolute accuracy of the angle-of-attack measurements is estimated to be within  $0.1^\circ$ .

~~CONFIDENTIAL~~

## PRESENTATION OF RESULTS

## Pressure Coefficients

All the pressures measured for the cylindrical body are presented in table 1. The longitudinal distribution of pressure coefficients for the cylindrical body at  $0^\circ$  angle of attack is presented in figure 3. Also shown in this figure is the pressure distribution for the curved body from references 1 and 3. The longitudinal distribution of pressure coefficient at the other angles of attack are presented in figure 4 at three Mach numbers (approximately 0.8, 1.00, and 1.13).

## Normal Force and Pitching Moment

A comparison of the normal-force and pitching-moment coefficients for the two bodies is presented in figures 5 and 6, respectively. All the data for the curved body were obtained from reference 1. In order to compare the pitching-moment characteristics of the two bodies, the moment coefficients were taken about the nose of the bodies.

The integral equation used to compute the normal-force coefficients for the cylindrical body was

$$C_{N_F} = - \frac{8L}{D_{\max}} \int_0^{0.5} \cos \theta \left[ \int_0^1 P \frac{D}{D_{\max}} d\left(\frac{x}{L}\right) \right] d\left(\frac{\theta}{2\pi}\right)$$

and that used to compute the pitching-moment coefficient was

$$C_{M_F} = \frac{8L}{D_{\max}} \int_0^{0.5} \cos \theta \left[ \int_0^1 P \frac{D}{D_{\max}} \left(\frac{x}{L}\right) d\left(\frac{x}{L}\right) \right] d\left(\frac{\theta}{2\pi}\right)$$

The coefficients presented at  $\alpha = 20^\circ$  could have been lowered as much as 25 percent of the value shown by changing the fairings of the graphical integrations. However, the data presented for the cylindrical body agree with the strain-gage data presented in reference 2. The fairing choice does not exist at  $\alpha \leq 8^\circ$  but this margin increases with angle of attack as the angle is increased from  $8^\circ$ .

The theoretical values of normal-force and pitching-moment coefficient shown in figures 5 and 6 were computed by the method described in reference 4. The equations for these coefficients may be written as follows:

$$C_{NF} = \frac{8S_b}{\pi D_{max}^2} \alpha + 4\eta c_{d_c} \frac{A_p}{\pi D_{max}^2} \alpha^2$$

$$C_{MF} = \frac{8}{\pi D_{max}^2} \left( \frac{Q}{L} - S_b \right) \alpha - 4\eta c_{d_c} \frac{A_p}{\pi D_{max}^2} \left( \frac{x_p}{L} \right) \alpha^2$$

The values of  $\eta$  and  $c_{d_c}$  used in the calculations for the cylindrical body were 0.7 and 1.2 and were chosen from reference 5 and references 6 and 7, respectively. The plan-form area  $A_p$ , the body volume  $Q$ , and the location of the centroid of the body plan-form area  $x_p$  were determined from graphical integrations of suitable geometric parameters.

#### Center of Pressure

A comparison of the center-of-pressure locations for the two bodies is presented in figure 7. The data for the cylindrical body were computed from the normal-force and pitching-moment coefficients of figures 5 and 6. The center-of-pressure data for the curved body were obtained from reference 1.

#### Detailed Aerodynamic Loads

The meridian normal-load distribution is presented for three Mach numbers (0.80, 1.00, and 1.13) through the angle-of-attack range in figure 8. This coefficient  $c_{nn}$  is defined in such a manner that the load perpendicular to the fuselage center line on a stringer section  $R_d(\theta)$  wide is  $c_{nn} q I R_{max} d(\theta)$ . Accordingly,  $c_{nn}$  is computed from the graphical integration along a body meridian as follows:

$$c_{nn} = - \int_0^1 \frac{D}{D_{max}} P d\left(\frac{x}{L}\right)$$

The longitudinal distribution of body cross-section normal loads at  $M = 1.00$  is presented in figure 9. The pressure data were computed by a graphical integration

$$c_n = \int_0^1 (P_L - P_U) d\left(\frac{y}{R}\right)$$

The theoretical values of  $c_n \frac{D}{D_{max}}$  were computed by the method of reference 4. The equation for a body of revolution may be written as follows:

$$c_n = \pi \left( \frac{dD}{dx} \right) \alpha + \eta c_d c \alpha^2$$

## DISCUSSION OF RESULTS

### Pressure Distribution

The pressures over the nose of both bodies, forward of the 20-inch station, are very similar to each other through the range investigated (figs. 3 and 4). Some of the differences observed near the tip of the nose are due to slight differences in the body shape at the apex. In general, the pressures over the rearward portions of the curved body are lower than those over the rearward portions of the cylindrical body. The typically characteristic rearward movement of the shock location with Mach number increases may be observed in figure 3. At  $M = 0.99$  the shock is located at approximately the 20-inch body station of the cylindrical body, whereas at  $M = 1.03$  the shock has moved to the 37-inch body station.

The compressions shown for the cylindrical body in figure 3 at  $M = 1.08$  and 1.10 at approximately the 30- and 34-inch stations, respectively, are probably due to the bow wave reflected from the tunnel wall and would not be evidenced in free flight. The expansions seen at the rear of the cylindrical body are caused by the air turning around the corner.

### Normal-Force Characteristics

As shown in figure 5, the cylindrical body develops greater normal force at a given angle of attack and Mach number than the curved body. The change in normal-force coefficient with Mach number is insignificant at the lower angles of attack, but there is a small increase in normal-force coefficient with Mach number at the higher angles of attack.

The prediction of the normal-force coefficients by the method of reference 4 is rather accurate at the lower angles of attack. In general, the measured values fall well below the theoretical values at the higher angles of attack. As mentioned previously, alternative fairings permissible for the integrations would result in even lower values for the measured data. The cross-flow Mach number is less than 0.4 at the highest

stream Mach number and at an angle of attack of  $20^{\circ}$ . Accordingly, the values of  $c_{d_c}$  are constant. Therefore, the theory does not predict the variation of normal force with Mach number shown by the measurements.

#### Pitching-Moment and Center-of-Pressure Characteristics

Examination of the pitching-moment data (fig. 6) indicates that the curved body exhibits either neutral or slightly unstable characteristics for the center of gravity at the nose or unstable characteristics for more rearward locations of the center of gravity. The cylindrical body exhibited more stable characteristics inasmuch as the center of pressure is located behind the 12-inch station for all conditions. It is also noted that the variation of the center-of-pressure location with Mach number is irregular and small (fig. 7).

The agreement of the measured pitching-moment coefficient with the theory is similar to that found for the normal-force coefficients. In general, when the normal-force coefficients are overpredicted, the negative pitching-moment coefficients are also overpredicted. Examination of the equations for  $C_{N_F}$  and  $C_{M_F}$ , given in the section entitled "Presentation of Results," indicates that the probable cause for the disagreement noted between the measured and predicted coefficients is associated with the values selected for  $\eta$  and  $c_{d_c}$ . Had lower values of  $c_{d_c}$  and  $\eta$  been used the agreement would have been better.

#### Detailed Load Characteristics

The maximum meridian load is developed at approximately the  $105^{\circ}$  meridian (fig. 8). It is observed that the loads do not vary appreciably with Mach number.

Examination of figure 9 indicates that although the cross-section normal loads over the forward portions of both bodies are similar, the loads over the rear portion of the cylindrical body are greater than those for the curved body. This is the reason that the pitching-moment characteristics of the cylindrical body are more stable than those for the curved body. The differences observed between the normal-force and pitching-moment characteristics for the two bodies are not caused by the added length of the cylindrical body.

Comparisons of the measured and theoretical values of cross-section normal-load coefficient indicate that the theory is in fair agreement with the measured values at angles of attack below  $12^{\circ}$ . The theoretical values show the same agreement at the forward and rearward portions of the cylindrical body. It is concluded that the errors between theory

and measurement for the cylindrical body at the higher angles of attack are due to the inadequacy of available data for selecting  $\eta$  and  $c_{d_c}$ . The disagreement between the theory and the measurements at the rearward end of the curved body may be due to sting interference. It should be noted that, at angles of attack above  $12^\circ$ , integration of the curves of figure 9 does not give as large a value for  $C_{N_F}$  as those plotted in figure 5. The data presented for the cylindrical body in figure 9 have been faired consistently with the data of reference 1, whereas the data of figure 5 agree with the strain-gage data of reference 2.

#### CONCLUSIONS

Analysis of the results obtained from a transonic wind-tunnel investigation of two bodies of revolution, one incorporating a cylindrical afterbody, the other incorporating a curved afterbody, indicates:

1. The pressures over the nose of both bodies are very similar although higher induced velocities exist over the rearward portions of the curved body; however, the cross-section normal-force coefficient is greater over the rearward portions of the cylindrical body.
2. At a given Mach number and angle of attack, the normal-force coefficient for the cylindrical body is greater than that for the curved body.
3. The center-of-pressure location was more rearward for the cylindrical body than for the curved body. Consequently, the cylindrical body exhibited more desirable stability characteristics.
4. The variation of normal-force and pitching-moment coefficients with Mach number is rather small, especially at the lower angles of attack.
5. The maximum meridian load for the cylindrical body occurs at approximately the  $105^\circ$  meridian.
6. The theoretical normal-force and pitching-moment characteristics of both bodies are in fair agreement with the results of this investigation.

TABLE I.- Concluded  
PRESSURE DATA. CYLINDRICAL BODY

(k)  $\mu = 1.13$

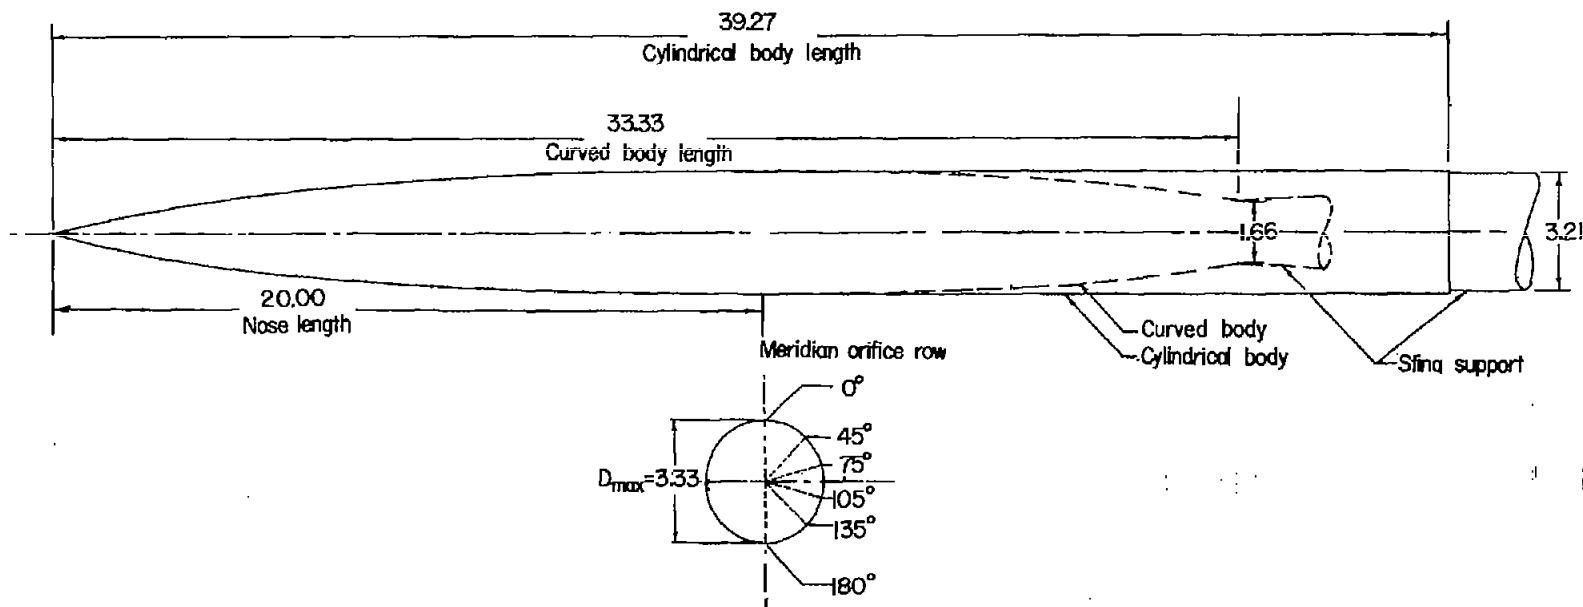

Figure 1.- Body details. (Linear dimensions in inches.)

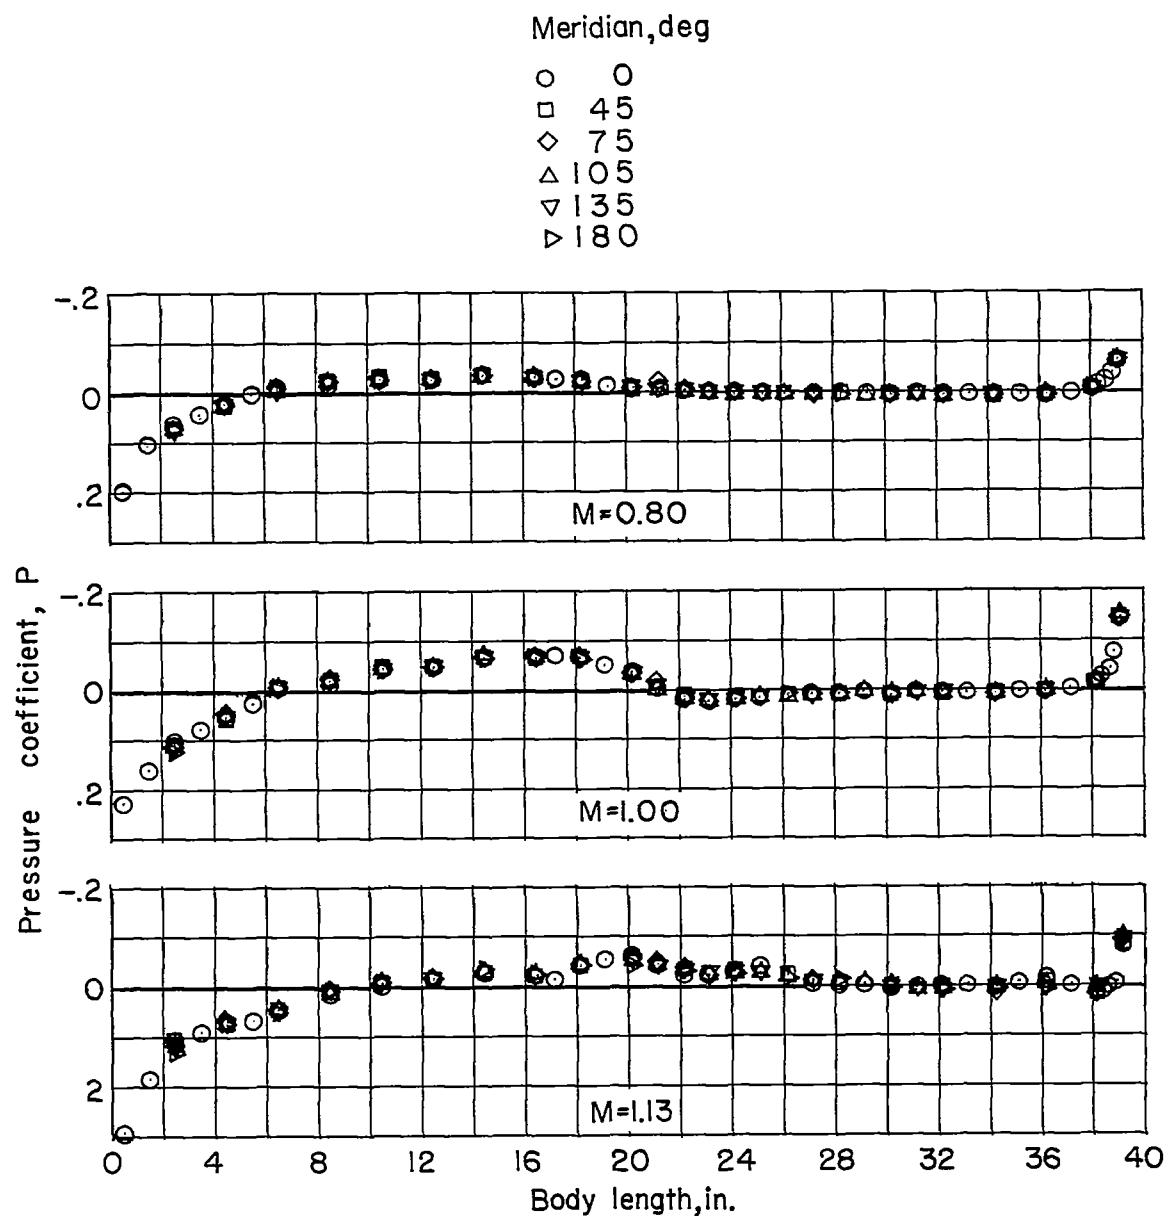

Figure 2.- Accuracy of pressure measurements.  $\alpha = 0^\circ$ .

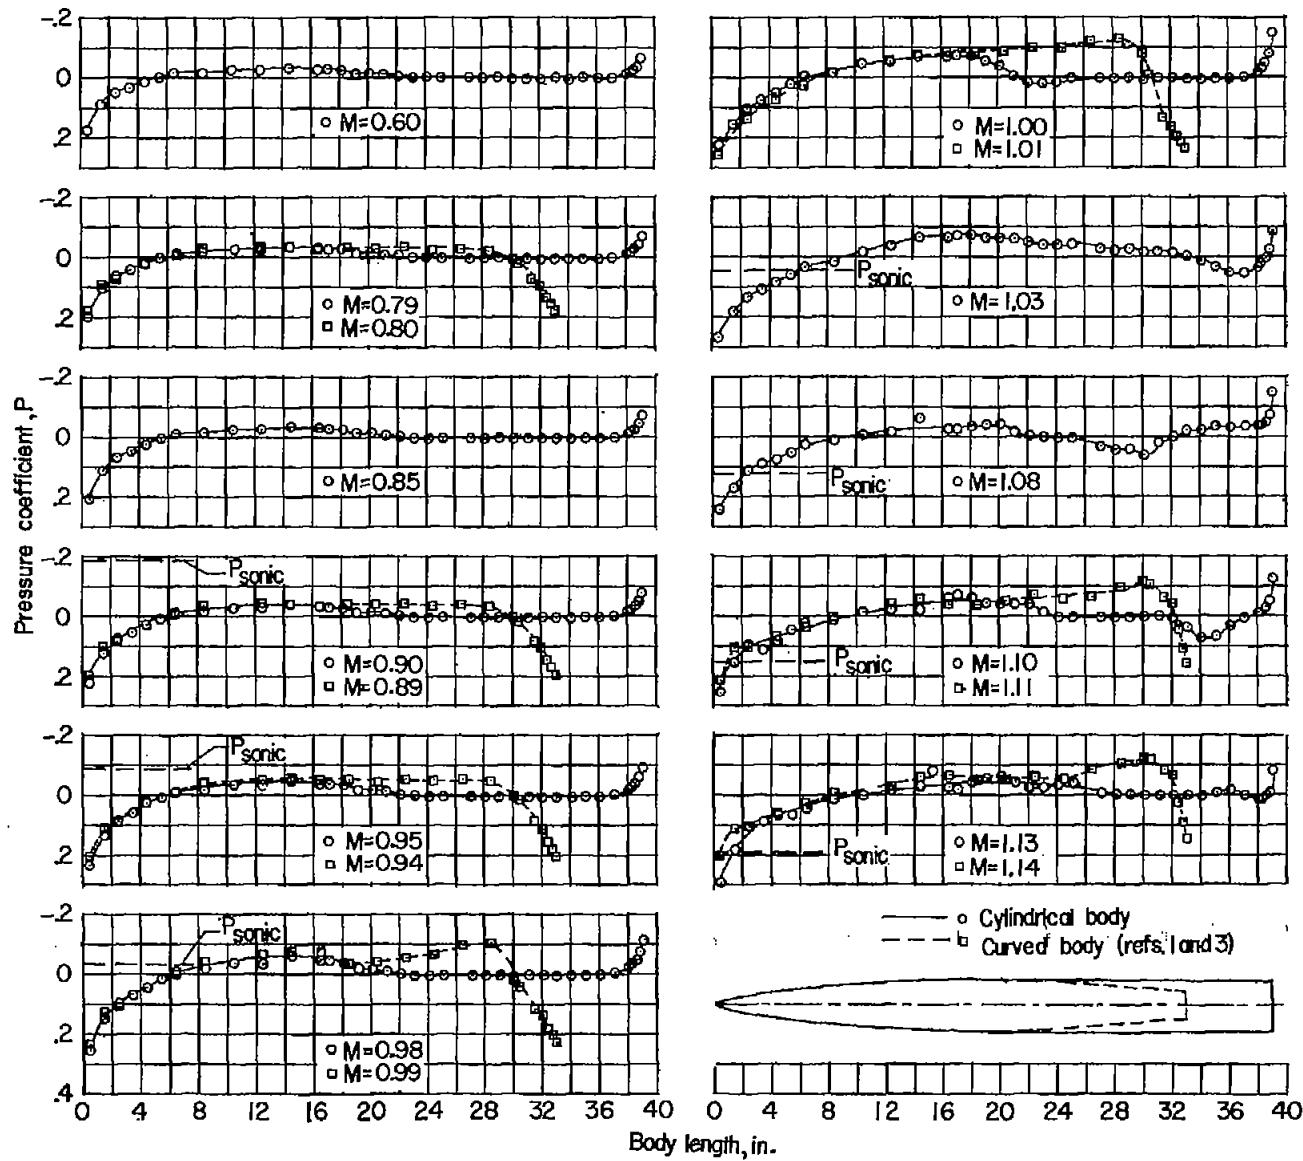

Figure 3.- Longitudinal pressure distribution at zero angle of attack.

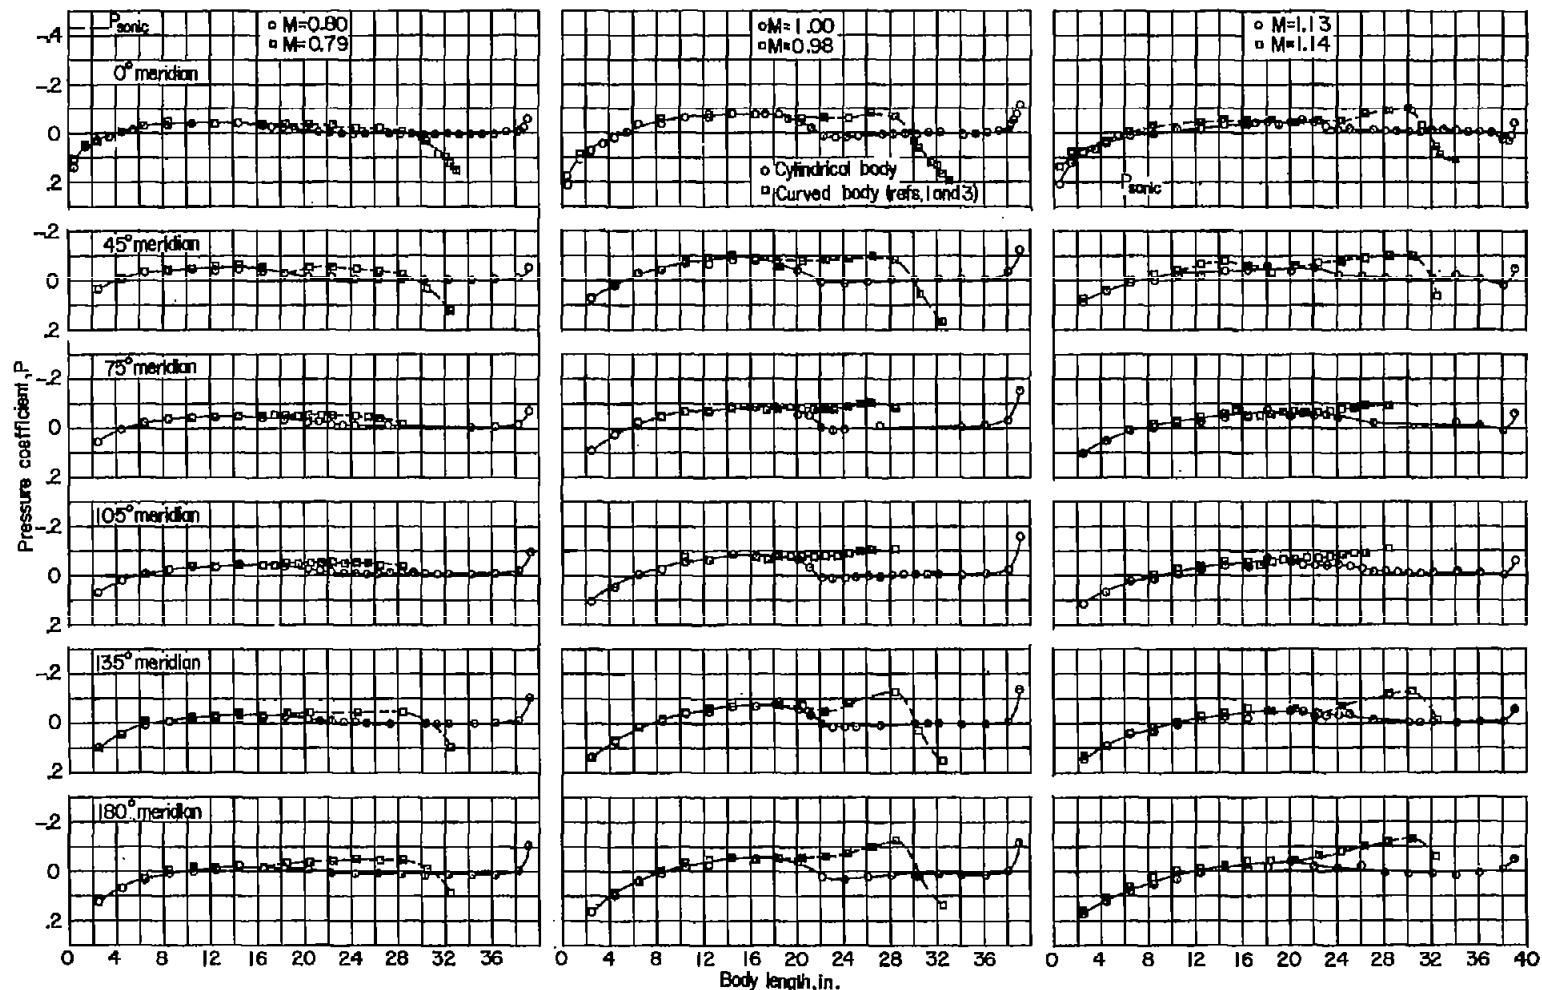

(a)  $\alpha = 4^\circ$ .

Figure 4.- Longitudinal pressure distribution at six radial stations.

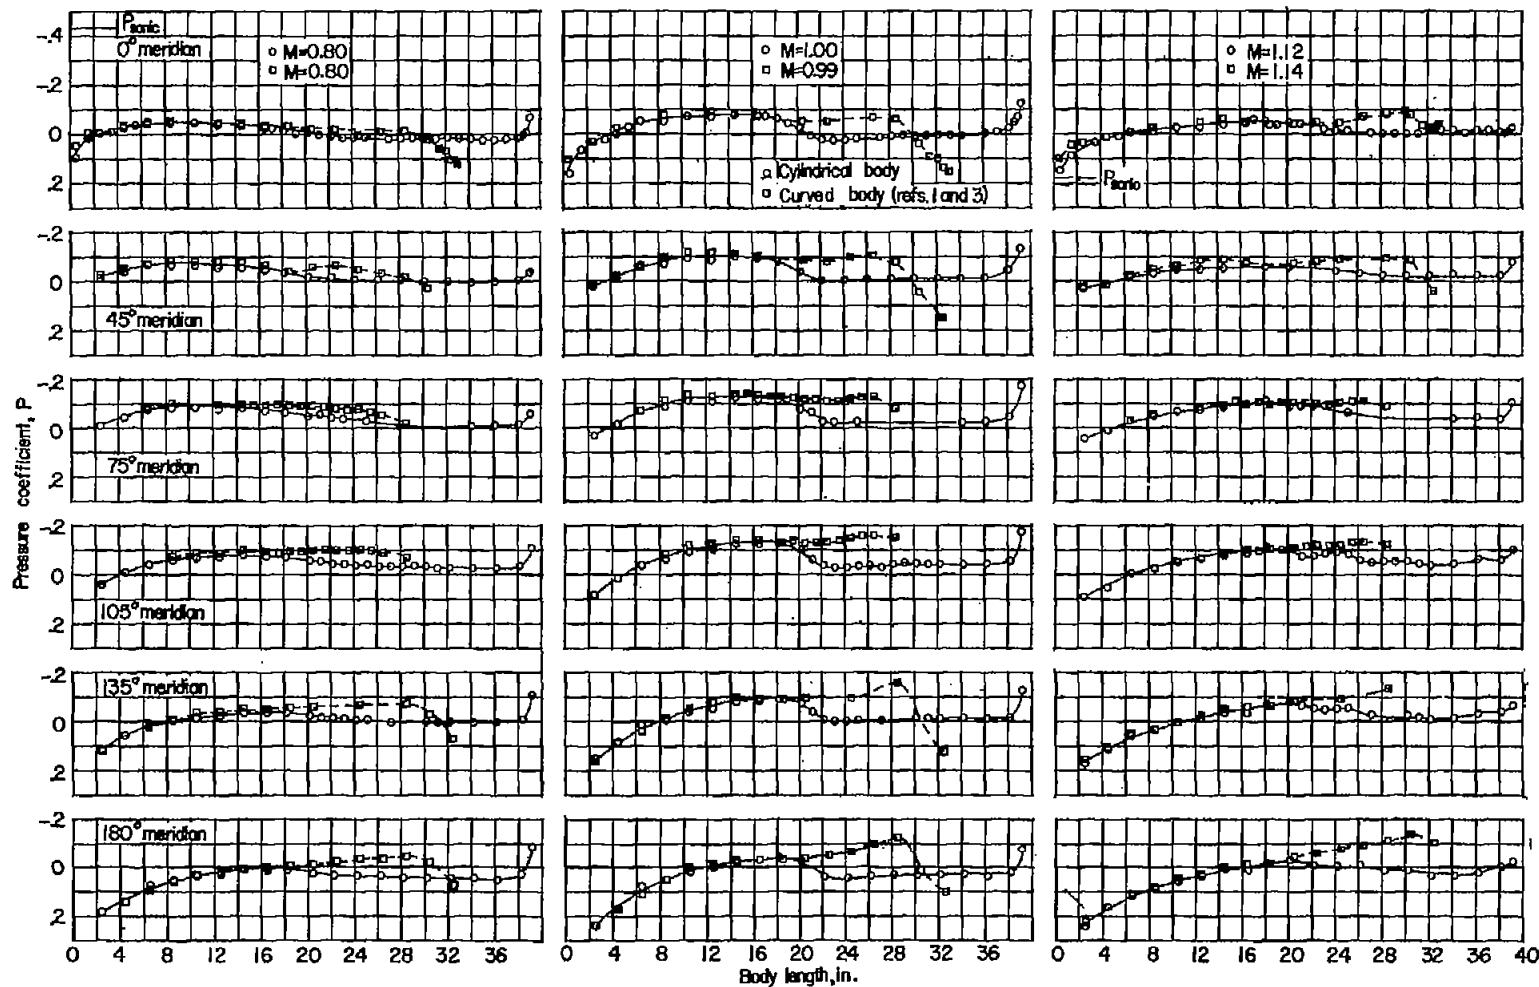

(b)  $\alpha = 8^\circ$ .

Figure 4--Continued.

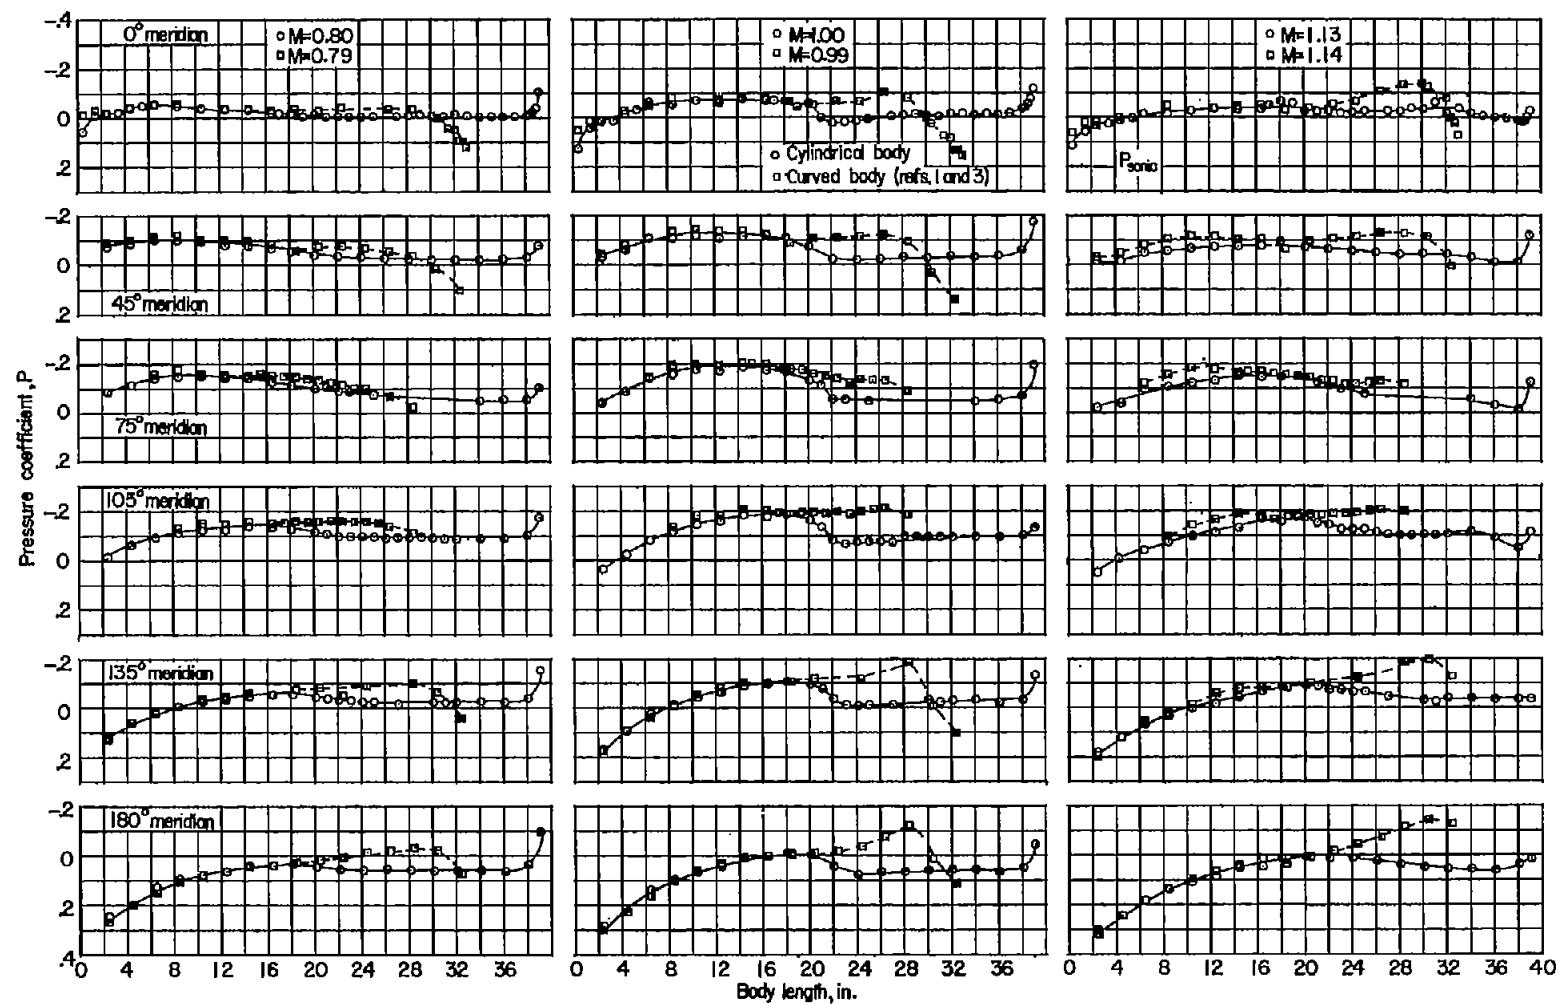

(c)  $\alpha = 12^\circ$ .

Figure 4.- Continued.

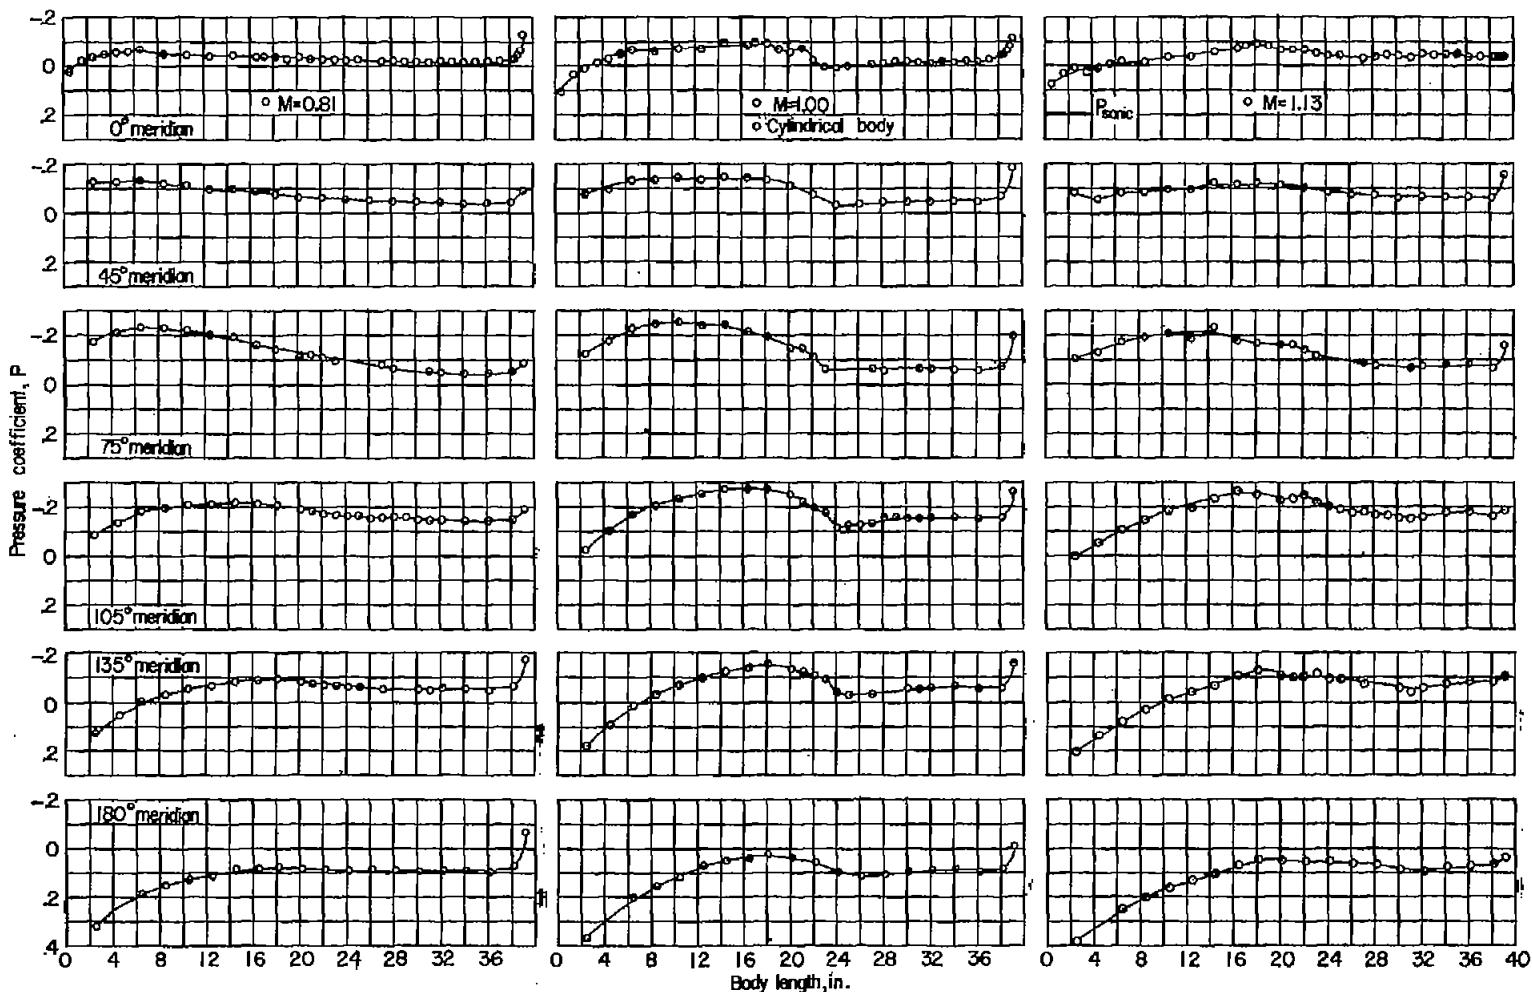

(d)  $\alpha = 16^\circ$ .

Figure 4.- Continued.

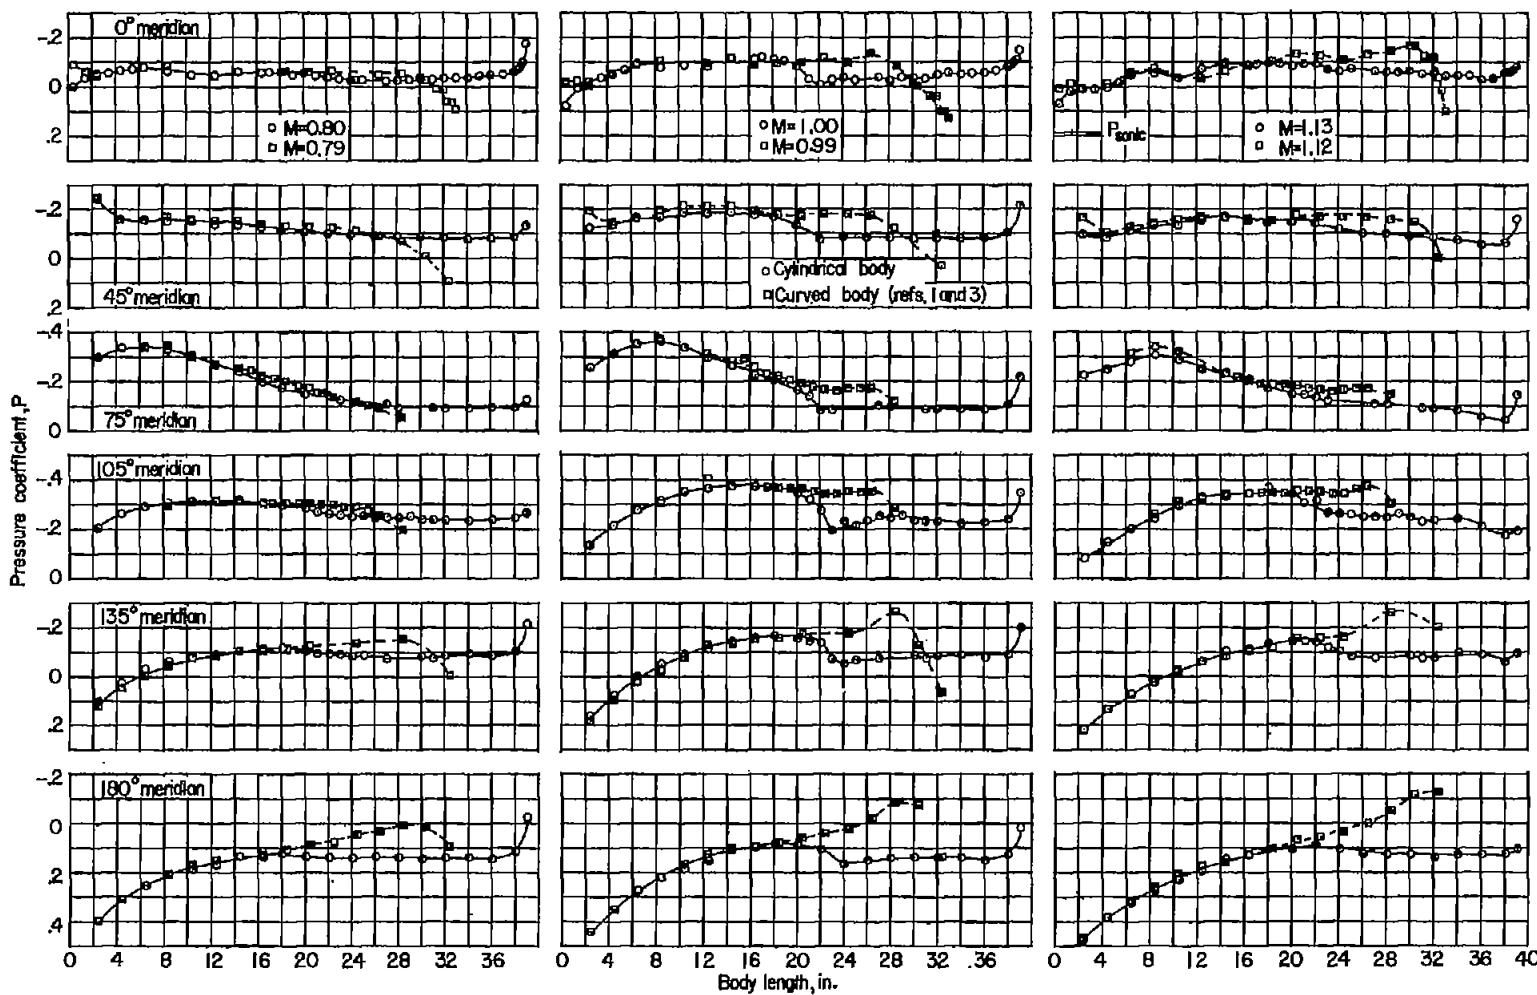

(e)  $\alpha = 20^\circ$ .

Figure 4.- Concluded.

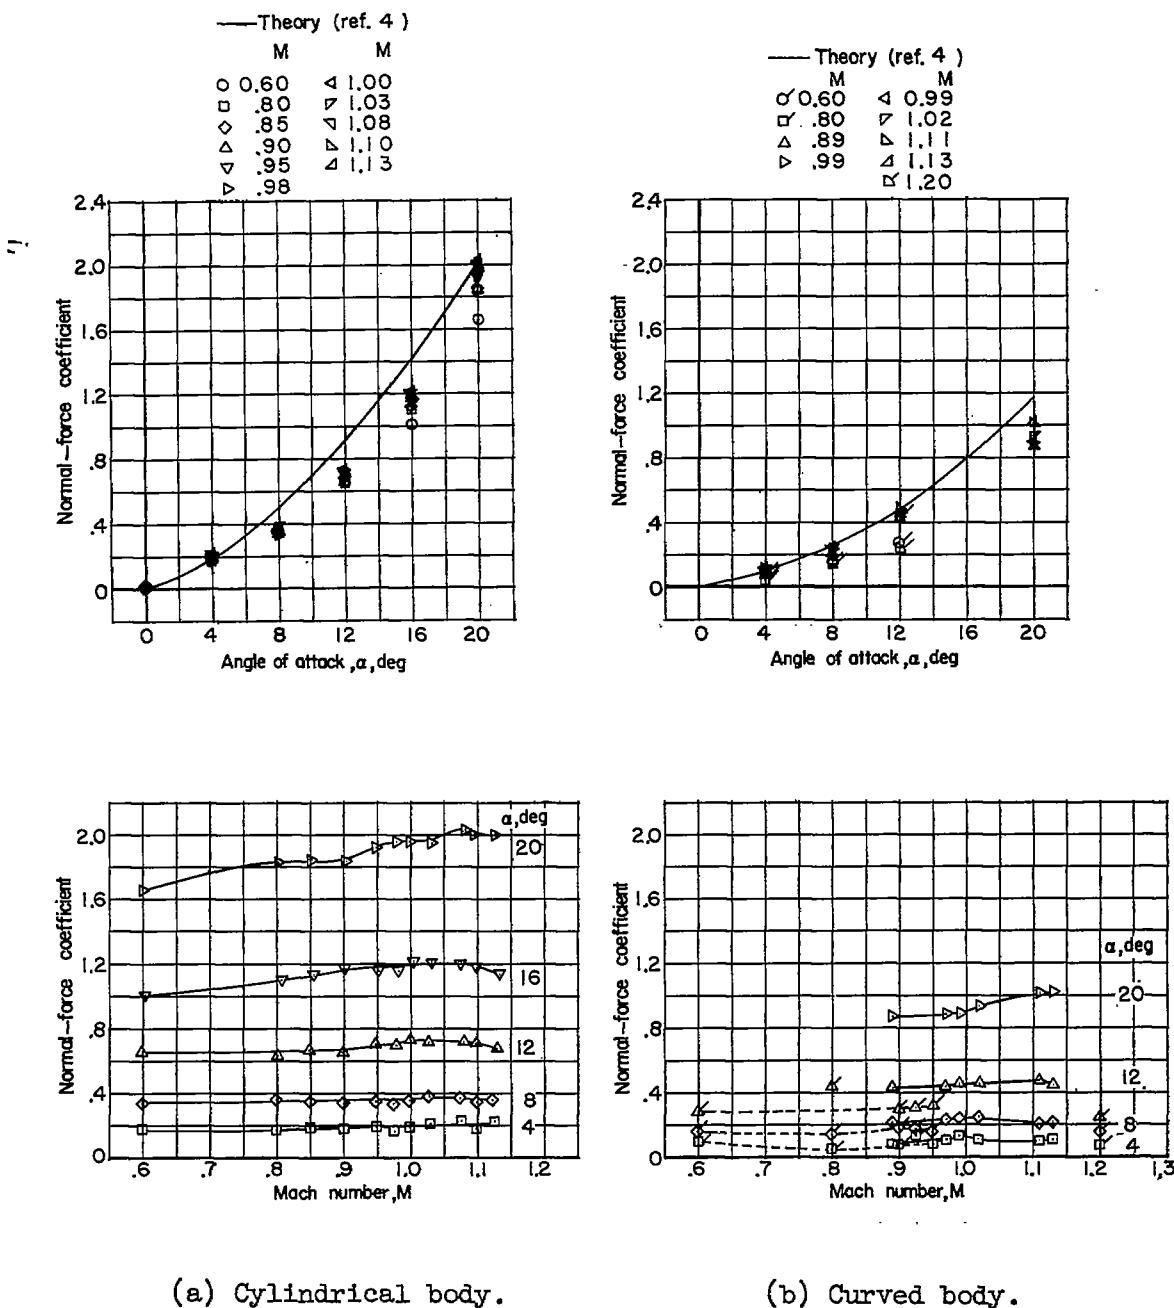

Figure 5.- Comparison of normal-force coefficients. (Flagged symbols represent data from closed-throat tunnel; unflagged symbols represent data from slotted-throat tunnel.)

~~CONFIDENTIAL~~

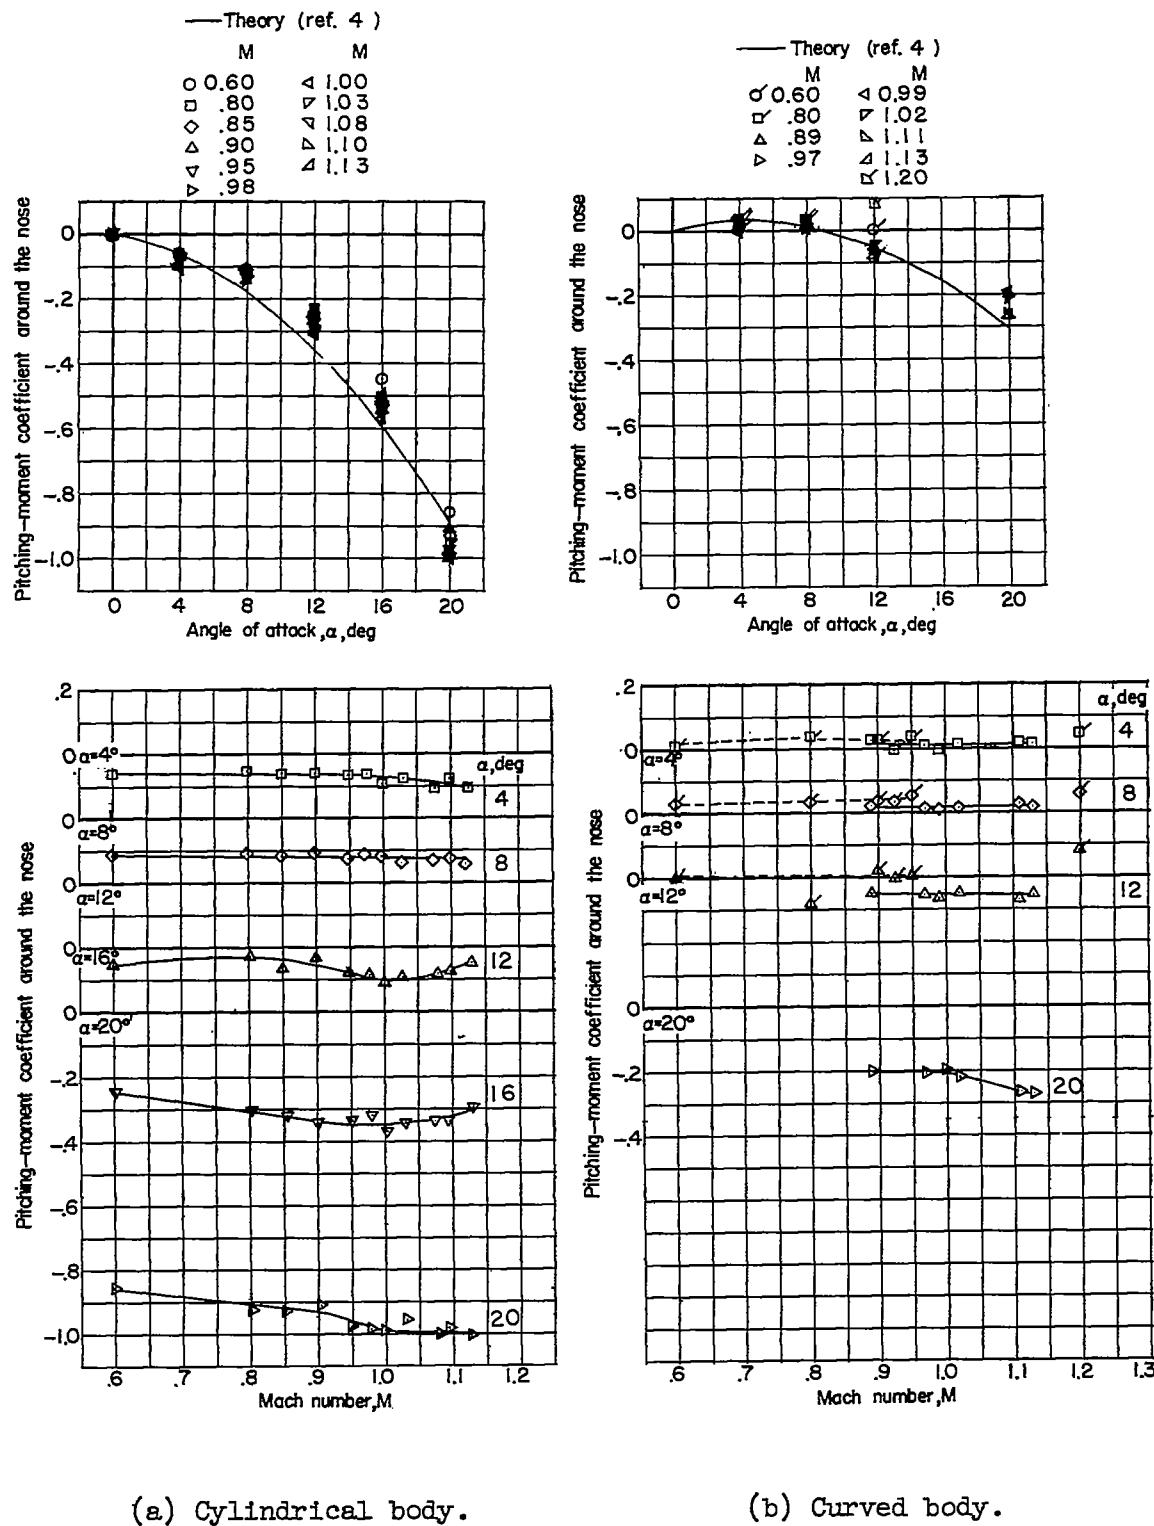

Figure 6.- Comparison of pitching-moment coefficients. (Flagged symbols represent data from closed-throat tunnel; unflagged symbols represent data from slotted-throat tunnel.)

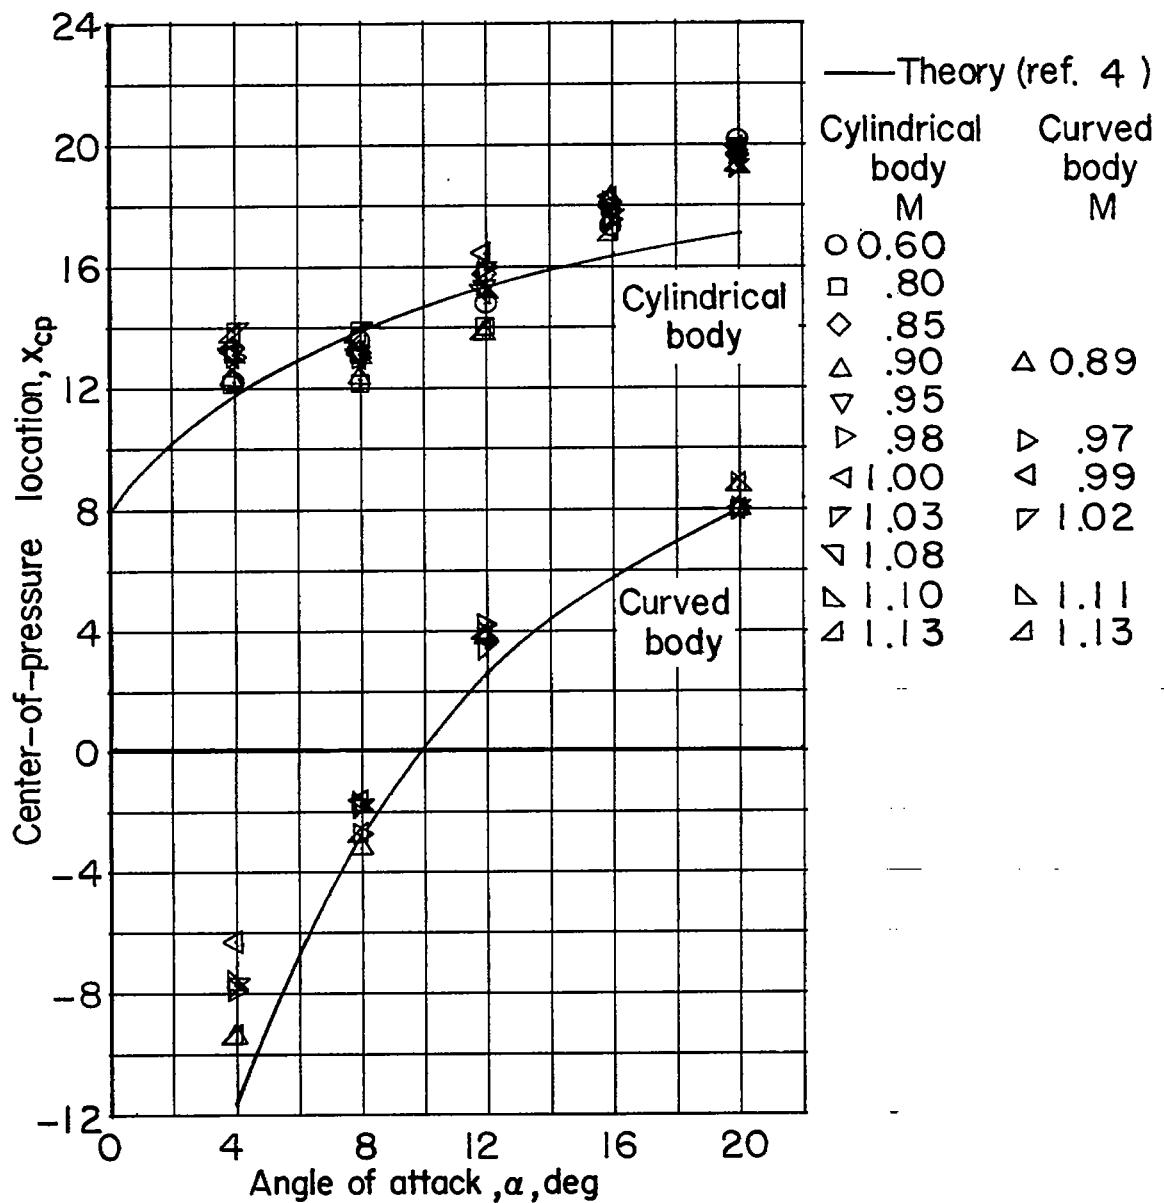

Figure 7.- Comparison of center-of-pressure locations.

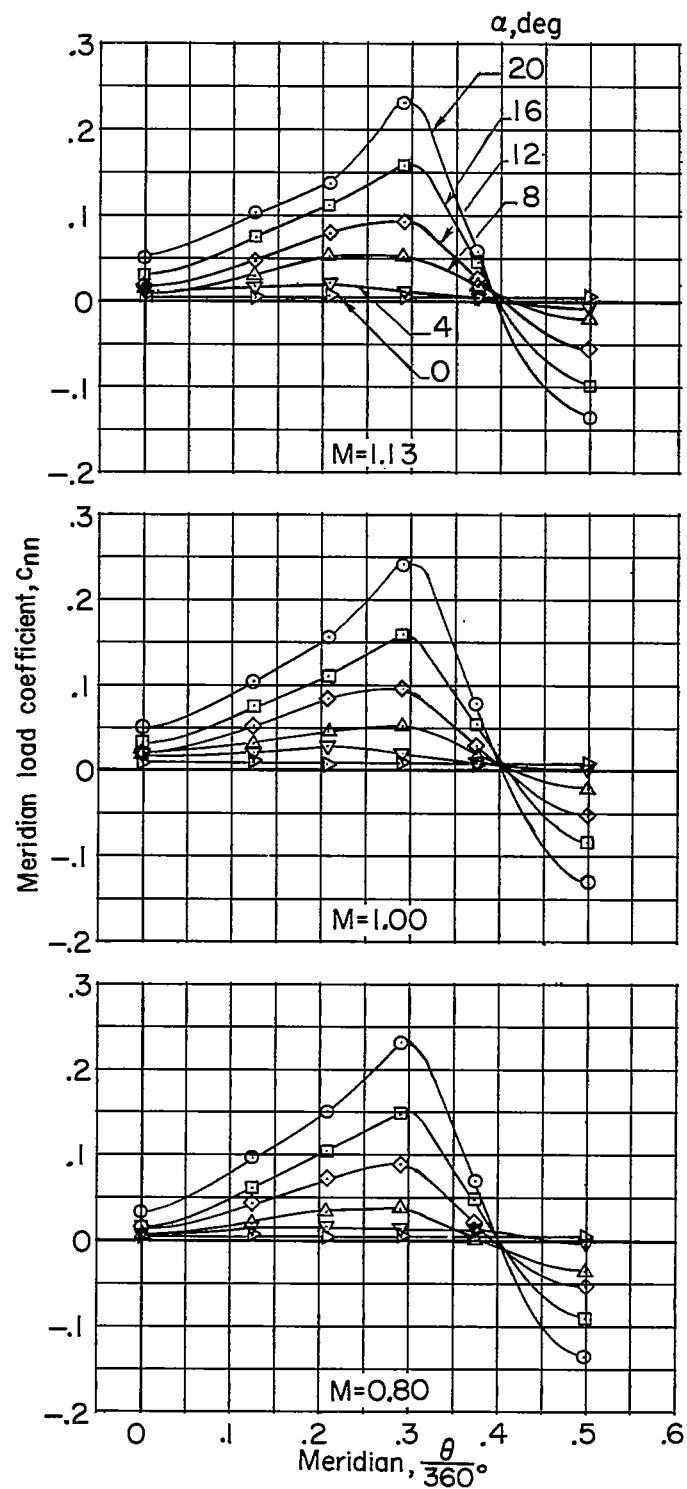

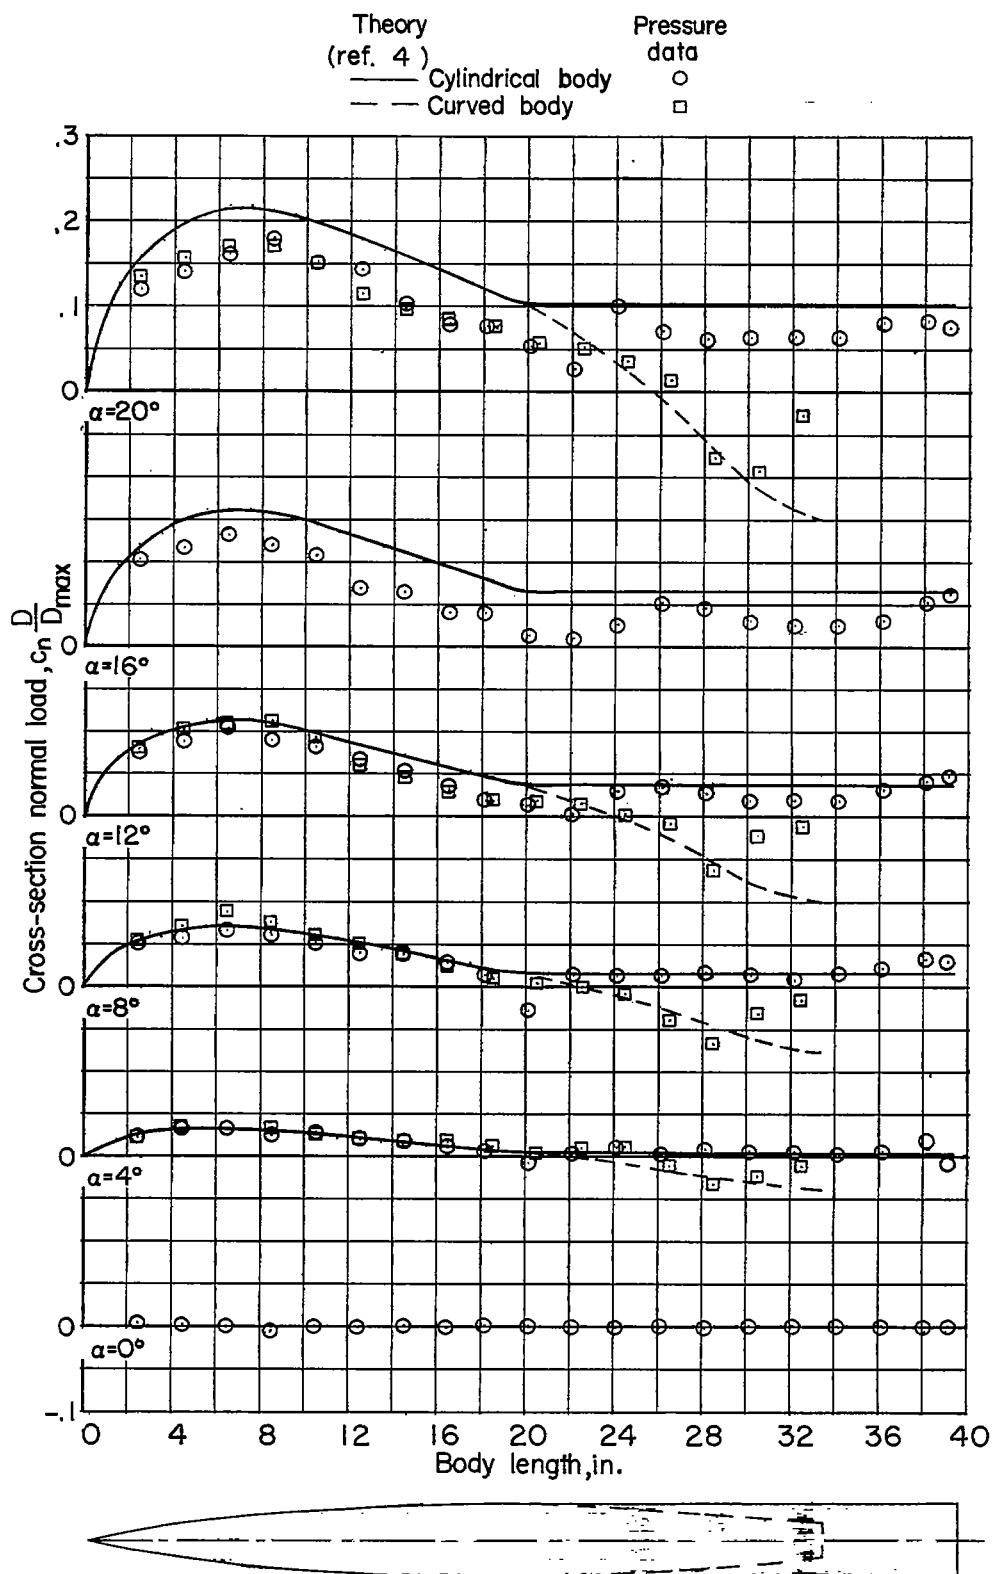

Figure 8.- Meridian load coefficient. Cylindrical body.

Figure 9.- Comparison of cross-section normal loads.  $M = 1.00$ .
